INTRODUCTION

Mental health has long occupied an ambivalent position within global health agendas. Despite decades of advocacy and accumulating evidence demonstrating its centrality to population health, mental health remains chronically underprioritised in policy, financing and service delivery. This marginalisation persists even as mental disorders constitute one of the leading causes of disability worldwide and exert profound social and economic consequences. The current moment represents a critical juncture: global mental health faces escalating demand, widening inequities and persistent structural barriers that demand a coordinated and transformative response.

Global Burden of Mental Disorders

Mental disorders, including depressive disorders, anxiety disorders, bipolar disorder, schizophrenia and substance use disorders, collectively account for a substantial proportion of the global burden of disease. The World Health Organization (WHO) estimates that more than one billion people worldwide live with a mental health condition, the majority of whom do not receive appropriate care [1,2]. Data from the Global Burden of Disease (GBD) Study demonstrate that mental disorders are among the leading contributors to years lived with disability (YLDs) across all regions, age groups and income settings, underscoring their pervasive and enduring impact on health-related quality of life [3].

Inequalities and Social Determinants

Importantly, the burden of mental ill-health is not evenly distributed. Social determinants such as poverty, gender inequality, conflict, displacement, exposure to violence and limited access to education and employment significantly shape both risk and outcomes. Mental health conditions are thus both a cause and a consequence of social inequity, reinforcing cycles of disadvantage that are particularly

pronounced in low- and middle-income countries (LMICs). Yet it is precisely in these settings that mental health systems are weakest, most fragmented and least resourced.

Impact of the COVID-19 Pandemic

The COVID-19 pandemic served as a global stress test for mental health systems, exposing longstanding vulnerabilities while simultaneously amplifying demand. In 2022, the WHO reported a 25% increase in the global prevalence of anxiety and depressive disorders during the first year of the pandemic [4]. This rise was driven by a confluence of factors, including social isolation, bereavement, economic insecurity, disruption of education and health services, and heightened uncertainty. Evidence suggests that women, young people and individuals already facing social or economic marginalisation experienced disproportionate mental health impacts, further widening existing inequalities [4,5].

Systemic Gaps in Mental Health Care

Despite the scale and urgency of need, national responses remain inadequate. The WHO Mental Health Atlas 2020 highlights profound disparities in mental health financing, workforce capacity and service availability across countries [6]. In many settings, mental health expenditure accounts for less than 2% of total health budgets, with a disproportionate share allocated to large psychiatric institutions rather than community-based and preventive services [6]. Workforce shortages are particularly acute: in some low-income countries, there are fewer than one mental health professional per 100,000 population, rendering meaningful access to care unattainable for large segments of the population.

Societal and Economic Consequences

The consequences of these systemic failures extend beyond individual suffering. Untreated mental illness is

associated with reduced educational attainment, diminished labour market participation, increased risk of physical comorbidity and premature mortality. At the societal level, poor mental health contributes to lost productivity, increased healthcare costs and substantial economic losses. Conversely, a growing body of evidence demonstrates that investment in mental health yields significant social and economic returns. Cost-effective interventions — including brief psychological therapies, pharmacological treatments for severe mental illness, and task-sharing models that train non-specialist providers — can be delivered at scale and integrated into primary health care with demonstrable benefits [1,5].

The Need for System-Level Transformation

Over the past decade, global mental health discourse has increasingly emphasised the need for system-level transformation. Key priorities include the integration of mental health into universal health coverage, decentralisation of services away from institutional models, expansion of community-based and culturally appropriate care, and the protection of human rights for people living with mental illness. The WHO's World Mental Health Report articulates a comprehensive framework for reform, calling for a shift from custodial care to person-centred, recovery-oriented and rights-based mental health systems [1].

Implementation Challenges and Emerging Risks

Nevertheless, progress remains uneven and fragile. While some countries have adopted national mental health strategies and expanded access to psychosocial services, implementation gaps persist due to insufficient funding, limited governance capacity and weak accountability mechanisms. Moreover, technological innovations such as digital mental health tools — though promising — risk exacerbating inequities if deployed without attention to accessibility, regulation and integration within public health systems.

CONCLUSION

Ultimately, the global mental health challenge is not one of insufficient knowledge, but of political will and prioritisation. The evidence base for effective and affordable interventions is robust; the ethical case for action is compelling. What is required now is sustained commitment from governments, international organisations and donors to elevate mental health to its rightful place within global health and development agendas [6].

Mental health must be recognised as a foundational pillar of health, wellbeing and social sustainability. Failure to act will perpetuate avoidable suffering and deepen global inequities. Meaningful reform, by contrast, offers an opportunity not only to reduce the burden of mental illness, but to advance broader goals of social justice, economic resilience and human development. The question is no longer whether transformation is possible, but whether the global community is willing to act with the urgency and scale that the evidence demands [1].

CONFLICT OF INTEREST

The author declares no conflicts of interest.
